Java `printf()` Method Quick Reference

System.out.printf("format-string", arg1, arg2, ...);

Format String:

Composed of literals and format specifiers. Arguments are required only if there are format specifiers in the format string. Format specifiers include: flags, width, precision, and conversion characters in the following sequence:

```
% [flags] [width] [.precision] conversion-character ( square brackets denote optional parameters )
```

Flags:

- : left-justify (default is to right-justify)
+ : output a plus (+) or minus (-) sign for a numerical value
0 : forces numerical values to be zero-padded (default is blank padding)
, : comma grouping separator (for numbers > 1000)
   : `space` will display a minus sign if the number is negative or a space if it is positive

Width:

Specifies the field width for outputting the argument and represents the minimum number of characters to be written to the output. Include space for expected commas and a decimal point in the determination of the width for numerical values.

Precision:

Used to restrict the output depending on the conversion. It specifies the number of digits of precision when outputting floating-point values or the length of a substring to extract from a String. Numbers are rounded to the specified precision.

Conversion-Characters:

- d : decimal integer [byte, short, int, long]
- f : floating-point number [float, double]
- c : character Capital C will uppercase the letter
- s : String Capital S will uppercase all the letters in the string
- h : hashcode A hashcode is like an address. This is useful for printing a reference
- n : newline Platform specific newline character - use `%n` instead of `
` for greater compatibility

Examples:

```
System.out.printf("Total is: $%.2f\n", dblTotal);
System.out.printf("Total: %10.2f: ", dblTotal);
System.out.printf("% 4d", intValue);
System.out.printf("%20.10s\n", stringVal);
```

String class `format()` method:

You can build a formatted String and assign it to a variable using the static `format` method in the String class. The use of a format string and argument list is identical to its use in the `printf` method. The format method returns a reference to a String. Example:

```
String grandTotal = String.format("Grand Total: $%.2f", dblTotal);
```
